

F2 Meta-learning against its own seed-matched control, 32 cells across 4 folds.
RMSE, positive means ANIL beats the control; whiskers are the 95% t-interval.

ANIL against a control that runs the same episode stream and outer-update count with no inner loop, so the only difference is whether adaptation happened during training (diagnostics/anil_report.py, results/misc/anil_*). Of 32 cells, 0 favour ANIL, 1 is significantly worse, 31 are within noise. Every cell warm-starts from an existing trunk, so this is meta-fine-tuning, and the meta-test fits a fresh adapter on the full held-out train fold, so nothing here measures few-shot behaviour.
