

F5 Ebola forecast on a disease the model never trained on. RMSE, lower is better; both arms beat the persistence floor.

5-seed mean, error bars the across-seed sd, country-macro RMSE in raw case counts (results/ebola/, results/naive/). Unadapted is the frozen trunk applied zero-shot, so it reads no Ebola label at any horizon; adapted fits the Ebola adapter, a genuine few-shot fit only at h3 and h5 (48 and 38 adaptation pairs). * On the L12 arm prereg E6 requires h10 and h15 to be reported zero-shot, never few-shot: h15 has zero adaptation pairs and h10 has only 18 on near-fully padded windows. These are point means with no interval, so nothing here is a significance claim; the pre-registered adapted-beats-persistence criterion was not met.
